The general effective medium equation (GEM) [1] and its modified form (mGEM) [2] have been widely fitted to effective dielectric constants of diphas composite dielectrics [3, 4]. GEM has the form:

$$\frac{V_l(\epsilon_l^{1/t} - \epsilon_m^{1/t})}{\epsilon_l^{1/t} + A\epsilon_m^{1/t}} + \frac{V_h(\epsilon_h^{1/t} - \epsilon_m^{1/t})}{\epsilon_h^{1/t} + A\epsilon_m^{1/t}} = 0 \quad (1)$$

where  $\epsilon_h$  and  $\epsilon_l$  are the relative dielectric constants of the high-dielectric phase and low-dielectric phase, respectively,  $V_h$  and  $V_l$  the volume fractions of the high-dielectric phase and low-dielectric phase ( $V_h + V_l = 1$ ),  $\epsilon_m$  the effective dielectric constant of the composite.  $t$  is an exponent parameter in GEM; and the other parameter  $A$  can be written as

$$A = \frac{1 - V_c}{V_c} \quad (2)$$

where  $V_c$  is the critical volume fraction of the high-dielectric constant phase. mGEM can be written as

$$\frac{V_l(\epsilon_l^{1/s} - \epsilon_m^{1/s})}{\epsilon_l^{1/s} + A\epsilon_m^{1/s}} + \frac{V_h(\epsilon_h^{1/t} - \epsilon_m^{1/t})}{\epsilon_h^{1/t} + A\epsilon_m^{1/t}} = 0 \quad (3)$$

An additional exponent parameter  $s$  is introduced here.

When fitting experimental data to predictive equations, the quantity of

$$\chi = \left[ \frac{1}{n - p} \sum_{i=1}^n \left( \frac{\epsilon_m - \epsilon_{equ}}{0.01\epsilon_m} \right)^2 \right]^{\frac{1}{2}} \quad (4)$$

is always minimized by varying the fittable parameters in the predictive equation. Here  $\epsilon_{equ}$  is the effective dielectric constant calculated by the predictive equation using appropriate variable parameters,  $n$  is the number of data points and  $p$  is the number of variable parameters in that equation [1].

Wu and McLachlan suggested that the fitting efficiencies of GEM and mGEM were nearly the same over the whole range of volume fractions [5]. We also observed the phenomenon that, when fitted to the same data set, GEM and mGEM had very close  $\chi$  values, which means similar fitting efficiencies [4]. At each data point, however, are the fitting efficiencies of GEM and mGEM nearly the same as well?

As  $\chi$  can only reflect fitting efficiency in whole range of volume fraction, after the parameters of a predictive

equation have been calculated, the quantity:

$$\alpha = \left( \frac{\epsilon_m - \epsilon_{equ}}{\epsilon_m} \right)^2 \quad (5)$$

is abstracted from  $\chi$  for each volume fraction to evaluate the fitting efficiency of that equation at each data point. The distribution pattern of  $\alpha$ , if it exists, so can be deduced.

We simulated effective dielectric constants of diphas composite dielectrics ( $\epsilon_m$ ) by Monte Carlo-finite element method on 2D square lattice for  $C = \epsilon_h$ ;  $\epsilon_l = 200, 500$  and  $700$  [4]. Then, for each  $C$  value, we calculated a group of parameters for GEM or mGEM. Using the quantity  $\alpha_{GEM} = \left( \frac{\epsilon_m - \epsilon_{GEM}}{\epsilon_m} \right)^2$ , we first evaluate

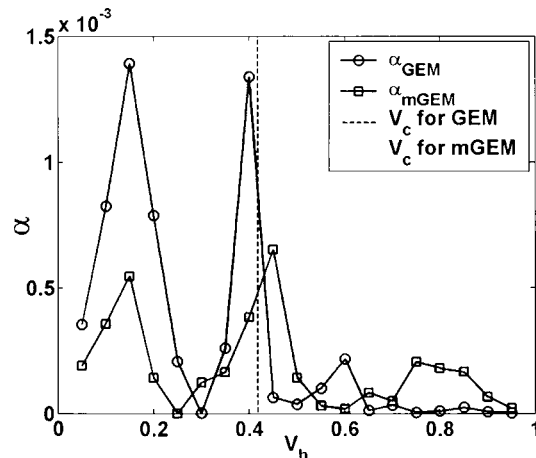

Figure 1 When  $C = 200$ ,  $\alpha_{GEM}$  vs.  $V_h$  and  $\alpha_{mGEM}$  vs.  $V_h$ .

Figure 2 When  $C = 500$ ,  $\alpha_{GEM}$  vs.  $V_h$  and  $\alpha_{mGEM}$  vs.  $V_h$ .

TABLE I Averages and standard deviations of  $\alpha$  for GEM and mGEM

|                 | GEM                    |                        | mGEM                   |                        |
|-----------------|------------------------|------------------------|------------------------|------------------------|
|                 | $V_h < V_c$            | $V_h > V_c$            | $V_h < V_c$            | $V_h > V_c$            |
| $\bar{\alpha}$  |                        |                        |                        |                        |
| $C = 700$       | $1.318 \times 10^{-3}$ | $1.053 \times 10^{-4}$ | $5.397 \times 10^{-4}$ | $2.593 \times 10^{-4}$ |
| $C = 500$       | $1.253 \times 10^{-3}$ | $2.126 \times 10^{-4}$ | $5.737 \times 10^{-4}$ | $2.887 \times 10^{-4}$ |
| $C = 200$       | $5.476 \times 10^{-4}$ | $1.552 \times 10^{-4}$ | $2.272 \times 10^{-4}$ | $1.668 \times 10^{-4}$ |
| STD of $\alpha$ |                        |                        |                        |                        |
| $C = 700$       |                        | $8.245 \times 10^{-4}$ |                        | $3.722 \times 10^{-4}$ |
| $C = 500$       |                        | $7.770 \times 10^{-4}$ |                        | $2.920 \times 10^{-4}$ |
| $C = 200$       |                        | $4.492 \times 10^{-4}$ |                        | $2.920 \times 10^{-4}$ |

Figure 3 When  $C = 700$ ,  $\alpha_{GEM}$  vs.  $V_h$  and  $\alpha_{mGEM}$  vs.  $V_h$ .

the fitting efficiency of GEM at each data point. In Figs 1–3, we plot  $\alpha_{GEM}$  vs.  $V_h$  for each  $C$  value. The critical volume fraction  $V_c$  for GEM is also shown in each figure. It is evident that, for each value, most of the  $\alpha_{GEM}$  computed when  $V_h < V_c$  are much greater than  $\alpha_{GEM}$  computed when  $V_h > V_c$  and that when  $V_h > 0.6$   $\alpha_{GEM}$  are especially small.

Thereafter, the fitting efficiency of mGEM at each data point was also examined by  $\alpha_{mGEM} = (\frac{\epsilon_m - \epsilon_{mGEM}}{\epsilon_m})^2$ . The plots of  $\alpha_{mGEM}$  vs.  $V_h$  are also shown in Figs 1–3 for each  $C$  value with  $V_c$  for mGEM marked as well. We can observe that for mGEM the discrepancies between  $\alpha_{mGEM}$  calculated when  $V_h < V_c$  and  $V_h > V_c$  are not as large as those for GEM.

In Table I, we present the average values of  $\alpha_{GEM}$ , ( $\bar{\alpha}_{GEM}$ ), calculated when  $V_h < V_c$  and  $V_h > V_c$ , and the standard deviation (STD) of  $\alpha_{GEM}$  for each  $C$  value the corresponding values for mGEM are also shown.

From this table we conclude that:

1. The fitting efficiency of GEM when  $V_h > V_c$  is much better than when  $V_h < V_c$ .

2. For mGEM, the fitting efficiency discrepancy with volume fraction is not so large as that of GEM.

3. Fluctuation of mGEM's fitting efficiency at each data point is much smaller than that of GEM, which is reflected by their STD values.

Therefore, if a predictive equation has to be chosen from GEM or mGEM to give the effective dielectric constants of diphase composite dielectrics, some suggestions are:

1. When volume fraction of the high-dielectric phase is very high, for example  $V_h$  is larger than 0.6 here, it is strongly advisable to use GEM to predictive effective dielectric constant.

2. When  $V_h$  is so low as smaller than  $V_c$ , mGEM will be a better choice for predictive equation.

3. When  $V_h$  is neither low nor high, mGEM should be used, for it will not give such large  $\alpha$  values as GEM does at mid-range values of  $V_h$ .

4. If only one predictive equation is to be chosen from GEM or mGEM for the whole range of  $V_h$ , mGEM may be the preferable choice; for its  $\alpha$  values have comparatively smaller fluctuation.
